

From admission relation to executable evidence

E1 separates authorization policies.

E2 tests the review boundary; E3 measures costs.

a Five distinguishing classes

- D_C candidate identity + context
- D_V proposal / authorized value roles
- D_F fresh predecessor
- D_B one complete successor
- D_S total field-source attribution

Omit a class: equal projections, distinct outcomes.

b Check relational persistence

Bounded relational analysis

legal steps + binding ablations

Persisted-state projection

intended steps + mapping mutants

Fault catalogue: admission, rejection, diagnosis

c Isolate the binding policy

E1: exact + reference agree on 165 cases

Context journal

15 admitted
ambiguous target

Exact + reference

15 rejected
exact target retained

**Equal-valued candidate substitution
is the separator.**

Under value/context policy:
exact binding adds 15 rejections.

d Locate review and cost boundaries

E2: review-to-request boundary

request substitutions admitted: 9 → 0
display-only substitutions: 3 each

E3: enforcement and query costs

admission · same-verifier trace access

Storage footprint measured separately.

conditional characterization → persisted checks
→ policy separator → review and cost boundaries
