

From admission relation to executable evidence

Each evidence layer answers a different question.

Constructed cases and timed calls keep separate denominators.

a Five distinguishing classes

- D_C candidate identity + context
- D_V proposal / authorized value roles
- D_F fresh predecessor
- D_B one complete successor
- D_S total field-source attribution

Omit a class: equal projections, distinct outcomes.

b Check relational persistence

Bounded relational analysis

72 declared command outcomes

Persisted-state projection

9 intended · 20 mapping mutants

35 cases: admission, rejection, diagnosis

c Isolate the binding policy

E1: 15 inputs × 11 families × 3 mechanisms

Context journal

15 instance violations
60 ambiguous answers

Exact + reference

0 instance violations
0 ambiguous answers

**Equal-valued candidate substitution
is the separator.**

Under value/context policy:
exact binding adds 15 rejections.

d Locate review and cost boundaries

E2: 60 browser cases

request substitutions admitted: 9 → 0
display-only substitutions: 3 each

E3: 22,400 timed observations

admission · same-verifier trace access

Storage footprint measured separately.

conditional characterization → persisted checks
→ policy separator → review and cost boundaries
